Incident report analysis

Instructions

As you continue through this course, you may use this template to record your findings after completing an activity or to take notes on what you've learned about a specific tool or concept. You can also use this chart as a way to practice applying the NIST framework to different situations you encounter.

Summary	Organization recently experienced a DDoS attack, which compromised the internal network for two hours until it was resolved. The company's cybersecurity team then investigated the security event. They found that a malicious actor had sent a flood of ICMP pings into the company's network through an unconfigured firewall. This vulnerability allowed the malicious attacker to overwhelm the company's network through a distributed denial of service (DDoS) attack.
Identify	A malicious actor targeted a company with an ICMP flood attack.The entire network was affected. And all critical network resources and devices are secured and restored to its functioning..
Protect	A new firewall rule to limit the rate of incoming ICMP packets.An IDS/IPS system to filter out some ICMP traffic based on suspicious characteristics
Detect	● Source IP address verification on the firewall to check for spoofed IP addresses on incoming ICMP packets ● Networking software to detect abnormal traffic patterns

Respond	For future security events, the cybersecurity team will isolate affected systems to prevent further disruption to the network. They will attempt to restore any critical systems and services that were disrupted by the event. Then, the team will analyze network logs to check for suspicious and abnormal activity. The team will also report all incidents to upper management and appropriate legal authorities, if applicable.
Recover	To recover from a DDoS attack by ICMP flooding, access to network services need to be restored to a normal functioning state. In the future, external ICMP flood attacks can be blocked at the firewall. Then, all non-critical network services should be stopped to reduce internal network traffic. Next, critical network services should be restored first. Finally, once the flood of ICMP packets have timed out, all non-critical network systems and services can be brought back online.
